Classical Billiard
Regular and Chaotic Dynamics

Regular Bunimovich stadium (chaotic)

- Energy and $p_x^2$ are conserved
- Equations of motion are integrable
- Predictable for infinite long times

- Only energy is conserved
- Equations of motion are not integrable
- Predictable for a finite time only
Tool: Poincaré Sections of Phase Space

- Parametrization of billiard boundary: $L$
- Momentum component along the boundary: $\sin(\phi)$

\[ L \]

\[ \sin(\phi) \]

conjugate variables
Sensitivity of the solutions of a deterministic problem with respect to small changes in the initial conditions is called **Deterministic Chaos**.

Beyond a fixed, for the system **characteristic time** becomes every prediction impossible. The system behaves in such a way as if not determined by physical laws but randomness.
Our Main Interest

- How are these properties of classical systems transformed into corresponding quantum-mechanical systems? → Quantum chaos?

- What might we learn from generic features of billiards and mesoscopic systems (hadrons, nuclei, atoms, molecules, metal clusters, quantum dots)?
The Quantum Billiard and its Simulation

\[ \Delta p \cdot \Delta x \geq \frac{\hbar}{2} \]

quantum billiard

electromagnetic cavity
Schrödinger ↔ Helmholtz

quantum billiard
2D microwave cavity: $h_z < \lambda_{\text{min}}/2$

$$\left(\Delta + k^2\right)\Psi = 0$$

$$\left(\Delta + k^2\right)E_z = 0$$

$$k = \sqrt{\frac{2mE}{\hbar^2}}$$

$$k = \frac{2\pi f}{c}$$

Helmholtz equation and Schrödinger equation are equivalent in 2D. The motion of the quantum particle in its potential can be simulated by electromagnetic waves inside a two-dimensional microwave resonator.
Superconducting Niobium Microwave Resonator
**Experimental Setup**

- Superconducting cavities
- LHe (T = 4.2 K)
- f = 45 MHz ... 50 GHz
- $10^3...10^4$ eigenfrequencies
- $Q = f/\Delta f \approx 10^6$
Stadium Billiard $\leftrightarrow n + ^{232}$Th

Transmission spectrum for the stadium billiard

$T = 2$ K

Spectrum of neutron resonances in $^{233}$Th + n
The first of these is intended to convey an idea of events arising out of a collision between a neutron and the nucleus. Imagine a shallow basin with a number of billiard balls in it as shown in the accompanying figure. If the basin were empty, then upon striking a ball from the outside, it would go down one slope and pass out on the opposite side with its original velocity. But with other balls in the basin, there would not be a free passage of this kind. The struck ball would divide its energy first with one of the balls in the basin, these two would similarly share their energies with others, and so on until the original kinetic energy was divided among all the balls. If the basin and the balls are regarded as perfectly smooth and elastic, the collisions would continue until the kinetic energy happens again to be concentrated upon a ball close to the edge. This ball would then escape from the basin and the remainder of the balls would be left with insufficient total energy for any of them to climb the slope.
Random Matrices $\leftrightarrow$ Level Schemes

Random Matrix

$$H = \begin{pmatrix}
H_{11} & \cdots & H_{1N} \\
\vdots & \ddots & \vdots \\
H_{N1} & \cdots & H_{NN}
\end{pmatrix}$$

Eigenvalues

$$H\phi_n = E_n\phi_n$$

nuclear data ensemble

Universal (generic) behaviour of the two systems
Universality in Mesoscopic Systems: Quantum Chaos in Hadrons

- Combined data from measured baryon and meson mass spectra up to 2.5 GeV (from PDG)

- Spectra can be organized into multiplets characterized by a set of definite quantum numbers: isospin, spin, parity, strangeness, baryon number, ...

- Scale: $10^{-16}$ m

Pascalutsa (2003)
Universality in Mesoscopic Systems: Quantum Chaos in Atoms

- 8 sets of atomic spectra of highly excited neutral and ionized rare earth atoms combined into a data ensemble
- States of same total angular momentum and parity

Scale: $10^{-10}$ m

Camarda + Georgopulos (1983)
Universality in Mesoscopic Systems: Quantum Chaos in Molecules

- Vibronic levels of NO₂
- States of same quantum numbers

Scale: $10^{-9}$ m

Zimmermann et al. (1988)
Conjecture of Bohigas, Giannoni + Schmit (1984)

How is the behaviour of the classical system transferred to the quantum system?

Answer: There is a one-to-one correspondence between billiards and mesoscopic systems on all scales.

For chaotic systems, the spectral fluctuation properties of eigenvalues coincide with the predictions of random-matrix theory (RMT) for matrices of the same symmetry class.

Numerous tests of various spectral properties (NNSD, $\Sigma^2$, $\Delta_3$, …) and wave functions exist.

Our aim: to test this conjecture in scattering systems, i.e. in open chaotic microwave billiards particularly in the regime of weakly overlapping resonances.
Microwave power is **emitted** into the resonator by antenna ① and the output signal is **received** by antenna ② → *Open scattering system*

- The antennas act as **single scattering channels**
- Absorption into the walls is modelled by **additive channels**

Transmission measurements: relative power from antenna $a \rightarrow b$

$$\frac{P_{\text{out,}b}}{P_{\text{in,}a}} = \left| S_{ba} \right|^2$$
Scattering Matrix Description

- Scattering matrix for both scattering processes

\[
\hat{S}(E) = \mathbb{1} - 2\pi i \ \hat{W}^T (E\mathbb{1} - \hat{H} + i\pi \ \hat{W}\hat{W}^T)^{-1}\hat{W}
\]

**Compound-nucleus reactions**

- nuclear Hamiltonian \(\leftarrow \hat{H} \rightarrow\) resonator Hamiltonian
- coupling of quasi-bound states to channel states \(\leftarrow \hat{W} \rightarrow\) coupling of resonator states to antenna states and to the walls

**Microwave billiard**

- Experiment: complex S-matrix elements

**RMT description**: replace \(\hat{H}\) by a GOE matrix for T-inv systems, GUE T-noninv systems
Use eigenrepresentation of

\[ \hat{H}_{\text{eff}} = \hat{H} - i\pi \hat{W} \hat{W}^T \]

and obtain for a scattering system with isolated resonances
\( a \rightarrow \text{resonator} \rightarrow b \)

\[ S_{ba} = \delta_{ba} - i \sum_{\mu} \frac{\sqrt{\Gamma_{\mu a} \Gamma_{\mu b}}}{f - f_{\mu} + (i/2)\Gamma_{\mu}} \]

Here:
- \( f_{\mu} \) = real part
- \( \Gamma_{\mu} \) = imaginary part \\
\{ of eigenvalues of \( \hat{H}_{\text{eff}} \) \\

Partial widths \( \Gamma_{\mu a}, \Gamma_{\mu b} \) fluctuate and total widths \( \Gamma_{\mu} \) also
Excitation Spectra

atomic nucleus

overlapping resonances
for $\Gamma/D > 1$

Ericson fluctuations

$\rho \sim \exp(E^{1/2})$

isolated resonances
for $\Gamma/D << 1$

$\rho \sim f$

Universal description of spectra and fluctuations:
Verbaarschot, Weidenmuller + Zirnbauer (1984)
Spectra and Correlation of S-Matrix Elements

- Regime of isolated resonances
- Overlapping resonances
- $\Gamma/D$ small
- $\Gamma/D \sim 1$
- Resonances: eigenvalues
- Fluctuations: $\Gamma_{coh}$

Correlation function:

$$C(\varepsilon) = \langle S(f)S^*(f + \varepsilon) \rangle - \langle S(f) \rangle \langle S^*(f + \varepsilon) \rangle$$
Ericson’s Prediction for $\Gamma > D$

- Ericson fluctuations (1960):
  $$\left| C(\varepsilon) \right|^2 \propto \frac{\Gamma_{coh}^2}{\Gamma_{coh}^2 + \varepsilon^2}$$

- Correlation function is Lorentzian

- Measured 1964 for overlapping compound nuclear resonances

- Now observed in lots of different systems: molecules, quantum dots, laser cavities, microwave cavities, …

- Different theoretical approaches: Ericson $\rightarrow$ energy and time domain
  \(\text{VWZ} \rightarrow \text{RMT}\)
  \(\text{Blümel & Smilansky} \rightarrow \text{semiclassical approach}\)

- Applicable for $\Gamma/D >> 1$ and for many open channels only
Fluctuations in a Fully Chaotic Cavity with T-Invariance

- Tilted stadium (Primack + Smilansky, 1994)

- GOE behaviour checked

- Measure full complex S-matrix for two antennas: $S_{11}$, $S_{22}$, $S_{12}$
Spectra of S-Matrix Elements in the Ericson Regime
Distributions of S-Matrix Elements the Ericson Regime

\[ z = \text{Re}\{S_{12}\} \]

\[ z = \text{Arg}\{S_{12}\} \]
Road to Analysis of the Measured Fluctuations

- Problem: adjacent points in $C(\varepsilon)$ are correlated

- Solution: FT of $C(\varepsilon)$ → uncorrelated Fourier coefficients $\tilde{C}(t)$
  Ericson (1965)

- Development: Non Gaussian fit and test procedure
Autocorrelation Function and Fourier Coefficients in the Ericson Regime

Exact RMT Result for GOE Systems

- Verbaarschot, Weidenmüller and Zirnbauer (VWZ) 1984 for arbitrary $\Gamma/D$:

- VWZ-integral: $C = C(T_p, D ; \varepsilon)$

\[
C_{ab}(\varepsilon) = \frac{1}{8} \int_0^\infty d\lambda_1 \int_0^\infty d\lambda_2 \int_0^1 d\mu(\lambda, \lambda_1, \lambda_2) \\
\times \exp\left(-i\pi\varepsilon(\lambda_1 + \lambda_2 + 2\lambda)/D\right) \\
\times J_{ab}(\lambda, \lambda_1, \lambda_2) \\
\times \prod_{\epsilon} \frac{(1 - T_\epsilon \lambda)}{(1 + T_\epsilon \lambda_1)(1 + T_\epsilon \lambda_2))^{1/2}}
\]

- Rigorous test of VWZ: isolated resonances, i.e. $\Gamma \ll D$

- First test of VWZ in the intermediate regime, i.e. $\Gamma/D \approx 1$, with high statistical significance only achievable with microwave billiards

- Note: nuclear cross section fluctuation experiments yield only $|S|^2$
Corollary

Present work:
S-matrix $\rightarrow$ Fourier transform $\rightarrow$ decay time (indirectly measured)

Future work at NIF:
Direct measurement of the decay time of an excited nucleus might become possible by exciting all nuclear resonances (or a subset of them) simultaneously by a short laser pulse.
Search for TRSB in Nuclei: Ericson Regime

**Improved Experimental Test of Detailed Balance and Time Reversibility in the Reactions $^{27}\text{Al} + p \leftrightarrow ^{24}\text{Mg} + \alpha$**

E. Blanke, H. Driller, and W. Glöckle

Abteilung für Physik und Astronomie, Ruhr Universität Bochum, D-4630 Bochum, Germany

and

H. Genz, A. Richter, and G. Schrieder

Institut für Kernphysik, Technische Hochschule Darmstadt, D-6100 Darmstadt, Germany

(Received 25 April 1983)

A new test of the principle of detailed balance in the nuclear reactions $^{27}\text{Al}(p,\alpha\gamma)^{24}\text{Mg}$ and $^{24}\text{Mg}(\alpha,p\gamma)^{27}\text{Al}$ at bombarding energies $7.3$ MeV $\leq E_p \leq 7.7$ MeV and $10.1$ MeV $\leq E_\alpha \leq 10.5$ MeV, respectively, is reported. Measured relative differential cross sections agree within the experimental uncertainty $\Delta = \pm 0.51\%$ and hence are consistent with time-reversal invariance. From this result an upper limit $\xi \leq 5 \times 10^{-4}$ (80% confidence) is derived for a possible time-reversal-noninvariant amplitude in the reaction.
T-symmetry breaking caused by a magnetized ferrite

Ferrite features ferromagnetic resonance (FMR)

Coupling of microwaves to the FMR depends on the direction $a \leftrightarrow b$

Principle of detailed balance: $|S_{ab}|^2 = |S_{ba}|^2$

Principle of reciprocity: $S_{ab} = S_{ba}$
Violation of Reciprocity

Clear violation of reciprocity in the regime of $\Gamma / D \approx 1$
Crosscorrelation function:

\[ C(S_{12}, S_{21}^*, \varepsilon) = \langle S_{12}(f) S_{21}^*(f + \varepsilon) \rangle - \langle S_{12}(f) \rangle \langle S_{21}^*(f) \rangle \]

- Determination of T-breaking strength from the data
- Special interest in first coefficient (\(\varepsilon = 0\))
Experimental Crosscorrelation Coefficients

\[ C(S_{12}, S_{21}^*) = \begin{cases} 
1 \text{ for GOE} \\
0 \text{ for GUE} 
\end{cases} \]

Data: TRSB is incomplete → mixed GOE/GUE system
Exact RMT Result for Partial T Breaking

RMT analysis based on Pluhař, Weidenmüller, Zuk, Lewenkopf and Wegner, 1995

\[ C(T_1, T_2, \tau_{\text{abs}}; D, \varepsilon, \xi) \]

\[ J_{ab} = \left\{ \frac{1}{(1 + T_a \mu_1)} \frac{1}{(1 + T_b \mu_2)} + \frac{1}{2} \frac{\mu_1}{(1 + T_a \mu_1)} \frac{1}{(1 + T_b \mu_2)} \left[ \frac{\mu_1}{(1 + T_a \mu_1)} + \frac{\mu_2}{(1 + T_b \mu_2)} \right] \right\} \]

\[ K_{ab} = \left( \frac{\varepsilon}{2} \right) \left\{ \frac{3 \lambda_3 (\lambda_2^2 - \lambda_1^2)}{\lambda_1^2} + \lambda_1 \mathcal{R} (4 \lambda_2^2 - 2 \mathcal{F}) \right\} \]

\[ \mathcal{F} = \frac{\varepsilon_+ (\lambda_2^2 - \lambda_1^2)}{\lambda_1^2} + \lambda_1 \mathcal{R} (\varepsilon_+ - 1) \]

\[ \lambda_1 = \lambda_2 \]
Exact RMT Result for Partial T Breaking

- RMT analysis based on Pluhař, Weidenmüller, Zuk, Lewenkopf and Wegner, 1995

\[ R \text{MT} \rightarrow H = H^s + i \left( \pi \xi / \sqrt{N} \right) H^a, \quad \xi = \begin{cases} 0 & \text{for GOE} \\ 1 & \text{for GUE} \end{cases} \]
Determination of T-Breaking Strength

Spectra of wave-dynamical systems show universal behaviour

Test of RMT predictions with microwave billiards

Investigated a chaotic T-invariant microwave resonator (i.e. a GOE system) both in the regime of weakly overlapping resonances ($\Gamma \lesssim D$) and in the Ericson regime ($\Gamma \gg D$)

Exponential decay and gaussian distribution of S-matrix elements found in the Ericson regime

Non-exponential decay and deviations from gaussian distribution of S-matrix elements found in the regime of weakly overlapping resonances

Data are limited by rather small FRD errors, not by noise

Stringent test of the VWZ theory of chaotic scattering using this large number of data points and a goodness-of-fit test
Investigated furthermore a chaotic T-noninvariant microwave resonator (i.e. a GUE system) in the regime of weakly overlapping resonances

Principle of reciprocity is strongly violated ($S_{ab} \neq S_{ba}$)

Data show, however, that TRSB is incomplete → mixed GOE / GUE system

RMT approach shows that full TRSB sets already in when the symmetry breaking matrix element is of the order of the mean level spacing
